Obstetrical Outcomes in SLE and APS

- Identify clinical need
- Describe experimental models elucidating pathophysiology
- Translate discoveries to patients

Implications for prediction of risk for and pathogenesis of pregnancy complications in SLE and/or APS patients and potential targets for treatment

HOSPITAL FOR SPECIAL SURGERY

Lupus is a disease more frequent in women (9:1 female:male) with typical onset during the childbearing years.

Until recently, many patients with SLE were told that they should never become pregnant.

SLE: Multi-system Autoimmune Disease

Picasso, Pregnant Woman (1950) *Hirshhorn Museum and Sculpture Garden, Washington, DC*

Pregnancy Complications in SLE

Hypertension

Preeclampsia

Placental insufficiency
Fetal growth restriction
Pregnancy loss

The presence of antiphospholipid antibodies (aPL) is the strongest predictor of pregnancy loss and other complications.

Picasso, Pregnant Woman (1950) *Hirshhorn Museum and Sculpture Garden, Washington, DC*

Subjects

- Pregnant women ≤12 weeks' gestation grouped according to the presence or absence of SLE and/or APL antibodies

  SLE+ APL+
  SLE+ APL-
  SLE- APL+
  SLE- APL-

SLE+ is defined as ≥4 ACR criteria for SLE

APL+ is defined as at least one of following documented twice 6 weeks apart in a core lab: ACL (IgG or IgM ≥ 40 units), anti-β2GPI (IgG or IgM ≥ 40 units) or Lupus anticoagulant

Controls (APL-/SLE-) must have had ≥1 normal pregnancy and no history of fetal death at >10 wks or >1 miscarriage at <10 wks gestation

- Age 18-45 years and able to give informed consent

HOSPITAL FOR SPECIAL SURGERY

Subjects

Exclusion Criteria

- Prednisone > 20 mg/day
- Renal disease (proteinuria >1000 mg/24 hr; serum Cr >1.2 mg/dl; RBC casts)
- Diabetes mellitus (Type I and Type II) antedating pregnancy
- Hypertension (blood pressure ≥140/90 mmHg)
- Multi-fetal pregnancy

Study Outcomes

The study outcome was a composite endpoint defined as the occurrence of one or more of the following events:

- Fetal death occurring after 12 weeks' gestation and not explained by chromosomal abnormalities, anatomic malformations, or congenital infections
- Neonatal death prior to hospital discharge and due to complications of prematurity and/or placental insufficiency
- Indicated preterm delivery prior to 36 weeks' gestation because of gestational hypertension, preeclampsia or placental insufficiency
- Small for gestational age (SGA) <5th %ile in the absence of anatomical or chromosomal abnormalities
- Preeclampsia defined as new onset of elevated blood pressure (≥140/90 mm Hg) AND proteinuria of 300 mg in a 24hr collection or ≥1+ on dipstick

Patient Assessments

Patients were seen monthly and 3 months post-partum:

- Physical examination and obstetric ultrasound
- Laboratory tests and urinalysis

HOSPITAL FOR SPECIAL SURGERY

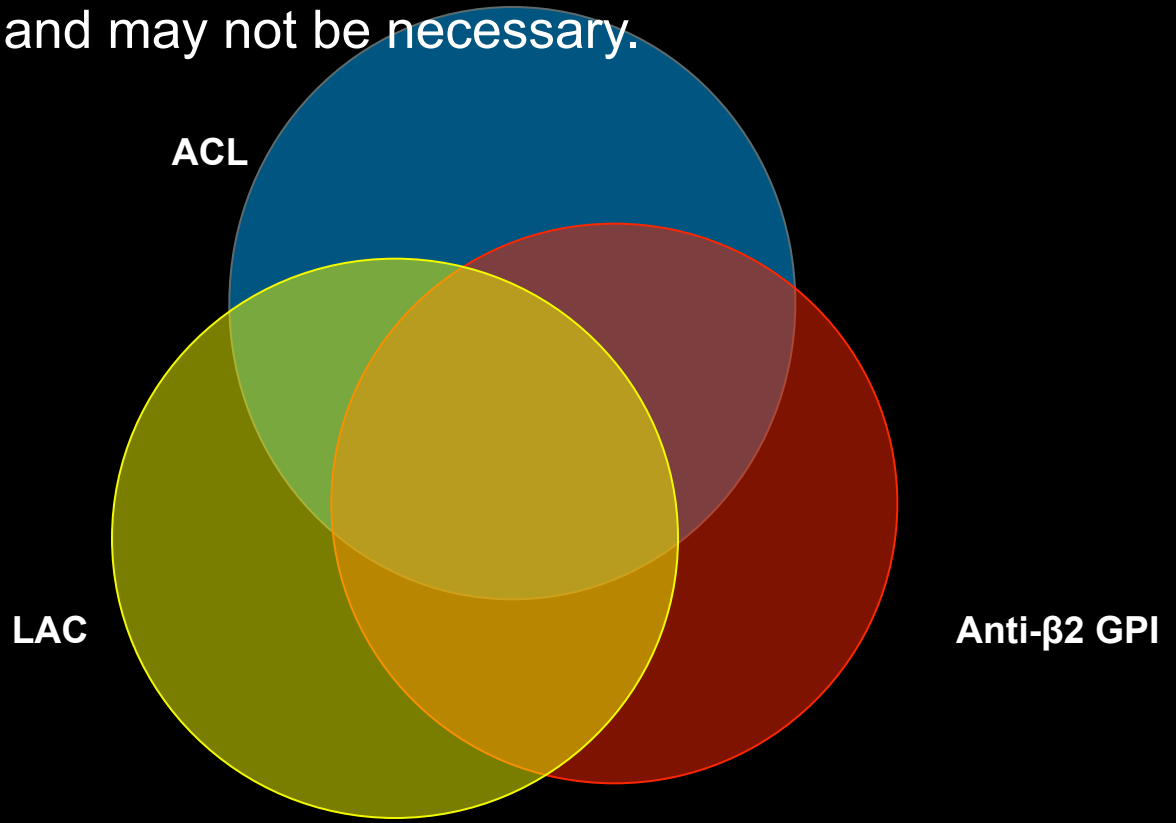
PROMISSE Discovery 1

Historical:

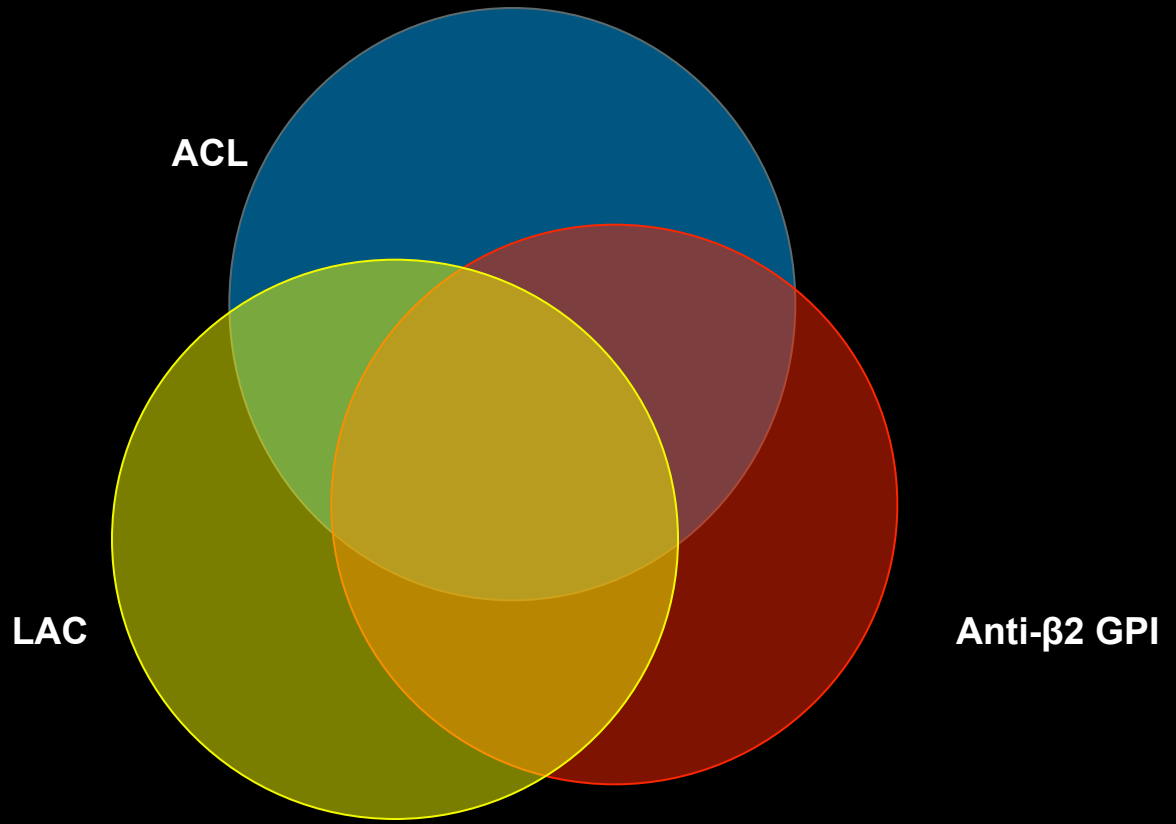
- Patients with all types of aPL antibodies were considered at similar risk for pregnancy complications.
- Patients with aPL antibodies are often treated with anticoagulation during pregnancy, but these drugs have side effects, are painful to administer, and may not be necessary.



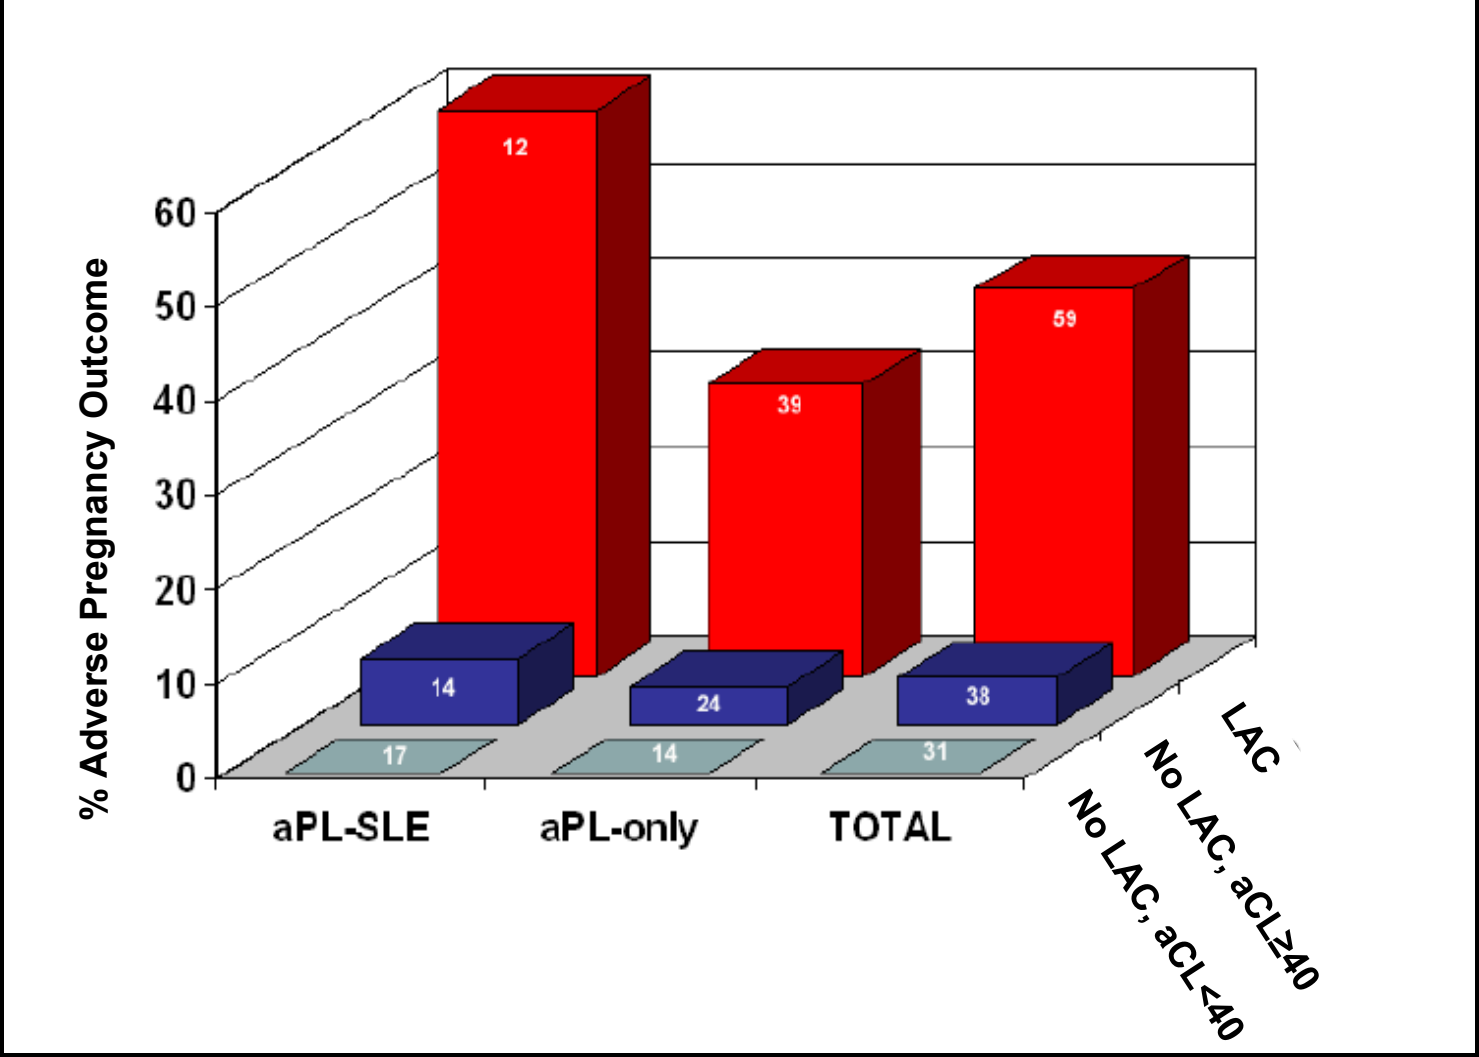
PROMISSE Discovery 1

Observation:

- Lupus anticoagulant (LAC) is the most powerful predictor of poor pregnancy outcomes in aPL-positive patients.



LAC is the Most Powerful Predictor of Outcome



- Predictive power aCL is due to its association with LAC
- Prior thrombosis and presence SLE are predictors of complications

Rethink treatment of aPL+ pregnant patients

Lockshin MD et al. Arthritis Rheum 64:2311-18, 2012

PROMISSE Discovery 2

Historical:

- SLE patients were discouraged from becoming pregnant.

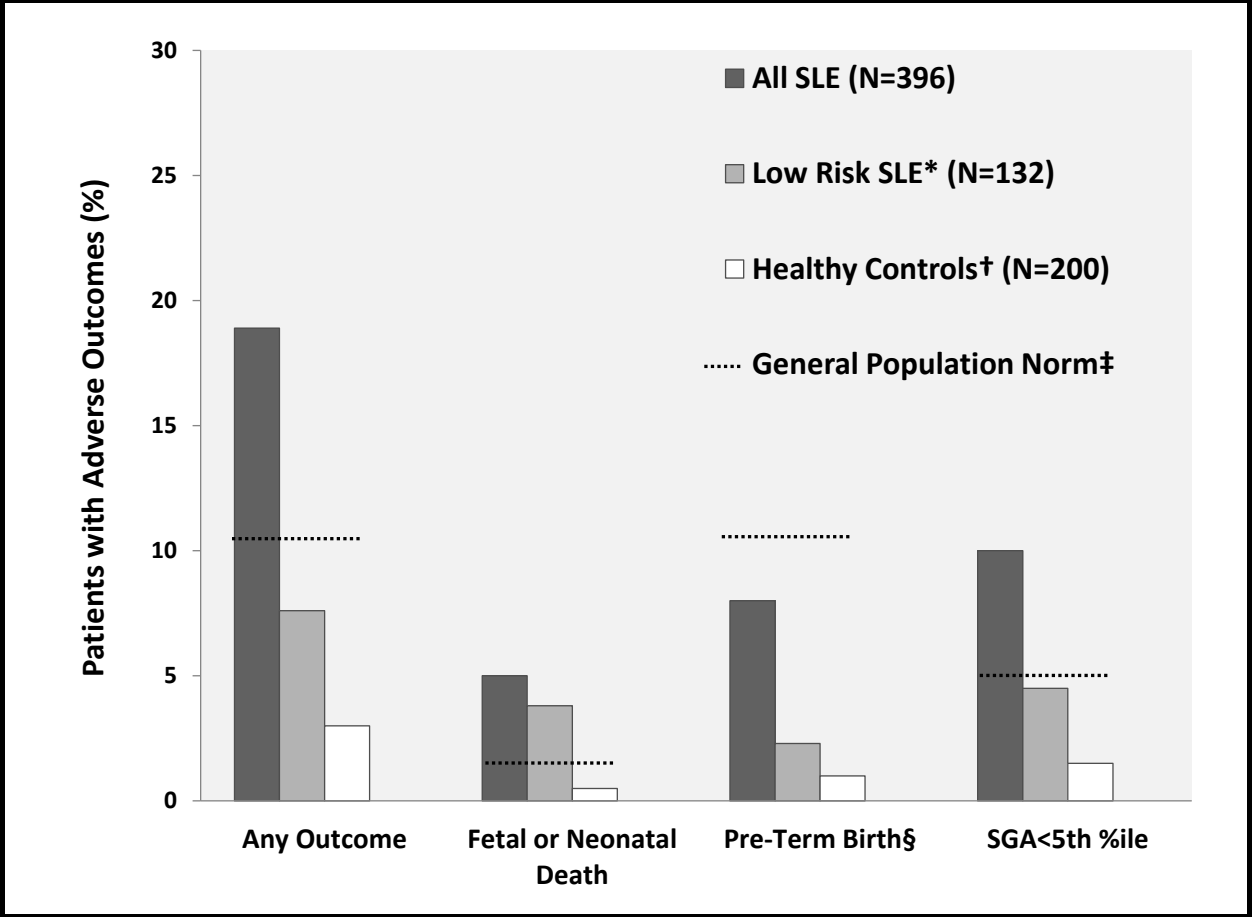
Observation:

- Mild/moderate flares developed in 20.0% (95% CI: 16.1% - 24.3%)
- Severe flares in 6.0% (95% CI: 3.8% - 8.8%)

PROMISSE Discovery 2

Observation:

- Among 396 SLE patients, one or more adverse pregnancy outcomes occurred in 19% of patients, fetal death (4%), neonatal death (1%), preterm delivery (8%), and SGA (10%).

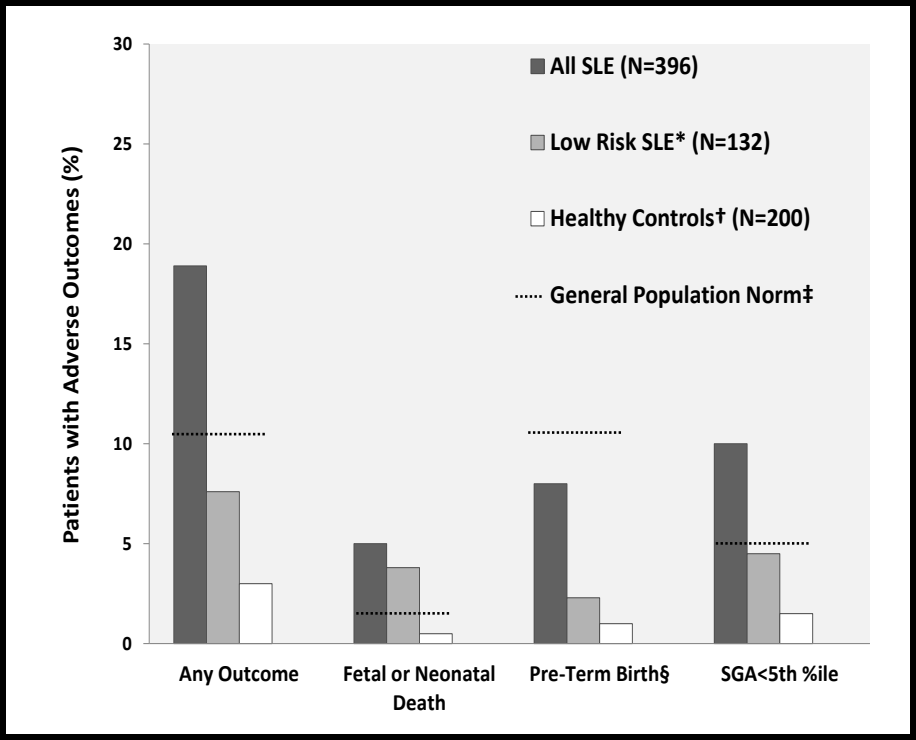


PROMISSE Discovery 2

Baseline predictors of adverse pregnancy outcomes (APO)

- Lupus Anticoagulant (LAC) (OR = 11.55, 95% CI: 4.47-29.86; P <0.0001)
- Antihypertensive use (OR = 6.21, 95% CI: 2.69-14.34; P <0.0001)
- Physician Global Assessment >1 (OR = 3.00, 95% CI: 1.36-6.62; P = 0.007)
- Non-Hispanic White was protective (OR = 0.46, 95% CI: 0.24-0.88; P = 0.02)
- Lower C3 level and flare in 2nd or 3rd trimesters

Among women with no baseline risk factors, APO rate was 7.6% (95% CI: 3.7% - 13.5%)



*** Low risk SLE patients are defined as non-Hispanic White, LAC negative, not moderately or severely active as supported by a PGA <1, and not treated with antihypertensive medications at baseline. They constitute a subset of the "All SLE" group.**

‡ Data were obtained from Roberts JM et al. NEJM 2010; 362:1282-1291.

§ Pre-term birth <36 weeks and indicated by gestational hypertension, preeclampsia, or placental insufficiency

PROMISSE Discovery 2

LIMITATION:

- Excluded patients with high disease activity.

CONCLUSIONS:

- SLE patients with stable, inactive disease can be reassured that severe flares are infrequent, and, in the absence of definable risk factors, pregnancy outcomes are favorable.

PROMISSE Discovery 3

Historical:

- No predictive tests to determine which patients will develop preeclampsia, a serious pregnancy problem.

Observation:

- Circulating anti-angiogenic factors are biomarkers that predict preeclampsia in patients with SLE and/or aPL antibodies.

HOSPITAL FOR SPECIAL SURGERY

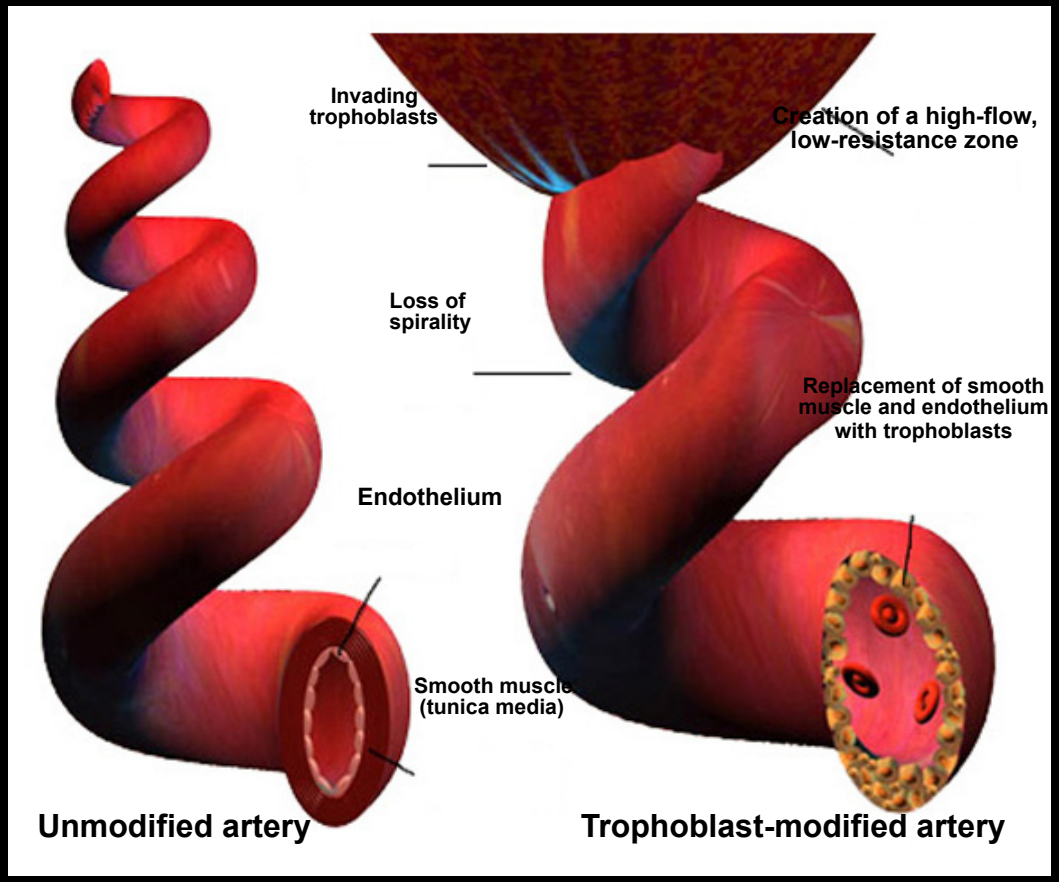
Preeclampsia

A pregnancy-specific disorder defined by the appearance of hypertension and proteinuria, usually after 20 weeks gestation.

- Complicates 4-5% of all pregnancies worldwide
- Claims the lives of > 60,000 mothers each year in developing countries

Preeclampsia

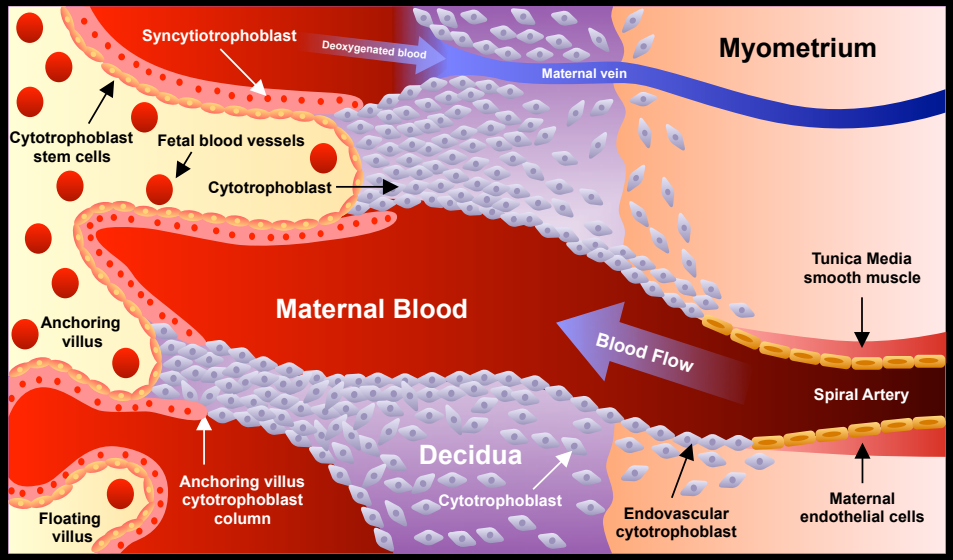
First stage: Abnormal placental development due to a failure of remodeling of uterine spiral arteries into dilated, flaccid vessels in early pregnancy, leading to underperfusion of the placental intervillous space.



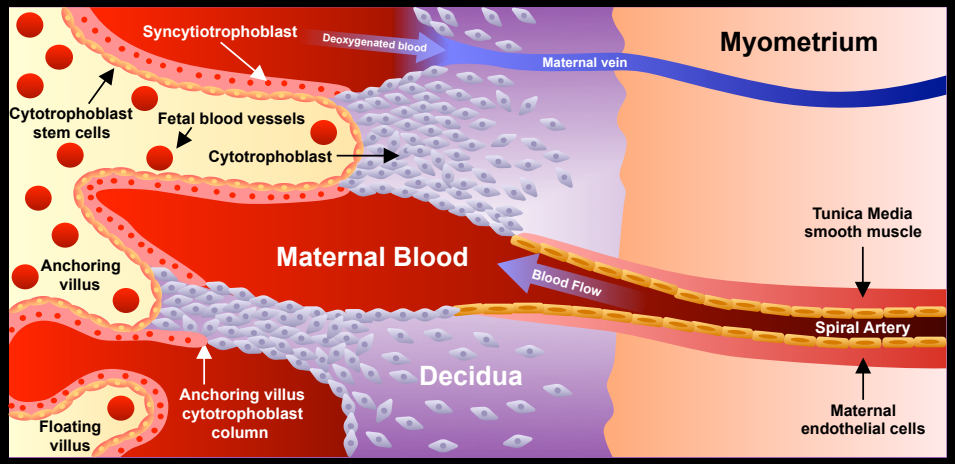
Preeclampsia **Normal**

Abnormal Placentation in Preeclampsia

Normal



Preeclampsia



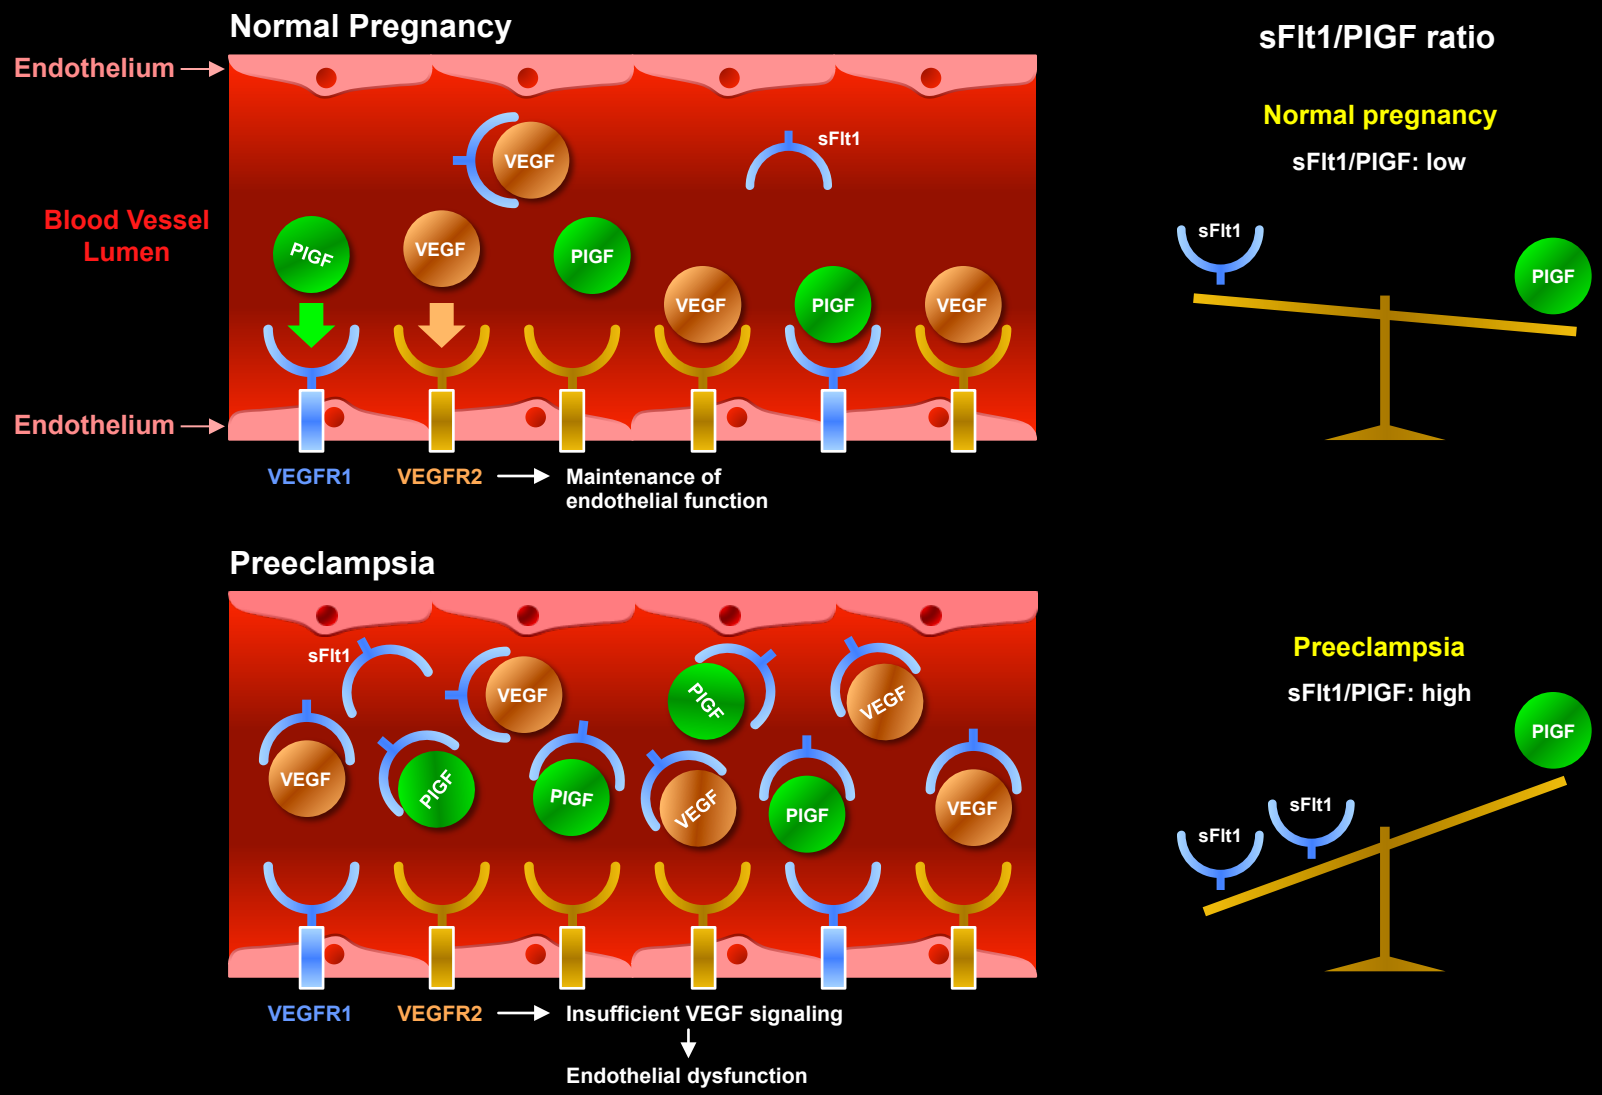
Adapted form Lam C, et al. *Hypertension.* 2005;46:1077-1085.

Preeclampsia

Second stage: Maternal systemic response to placental hypoperfusion, characterized by maternal hypertension, proteinuria, and other end-organ manifestations attributed to widespread **maternal endothelial dysfunction** mediated by placental secretion of **anti-angiogenic factors**.

Picasso, Pregnant Woman (1950) *Hirshhorn Museum and Sculpture Garden, Washington, DC*

Preeclampsia:
A Disorder of Angiogenic Dysregulation



PIGF, placental growth factor; VEGF, vascular endothelial cell growth factor; sFlt1, soluble VEGFR1

Adapted from Hagmann H et al. *Clin Chem.* 2012;58:837

Angiogenic Factors: Experimental Models of Preeclampsia

- Overexpression of sFlt1 in pregnant mice, rats and baboons leads to the classical manifestations of preeclampsia.[1,2]
- Symptoms of preeclampsia (proteinuria and hypertension) and changes in endothelial cell morphology are seen in cancer patients treated with VEGF antagonists.[3]

1. Maynard SE. 2003. J Clin Invest 111: 649
2. Gilbert JS 2007. Hypertension 50:1142
3. Ermina V 2008. N Engl J Med 358:1129

Angiogenic Factors: Prediction and Diagnosis of Preeclampsia

- Cross-sectional case-control studies showed sFlt1 and sFlt1/PlGF ratios to be higher in those destined for preeclampsia[1-4]

  Significant differences occurred 6 weeks or less before clinical manifestations.

- In a small series of SLE patients, sFlt1 measured once between 22-32 weeks was higher in preeclampsia.[5]

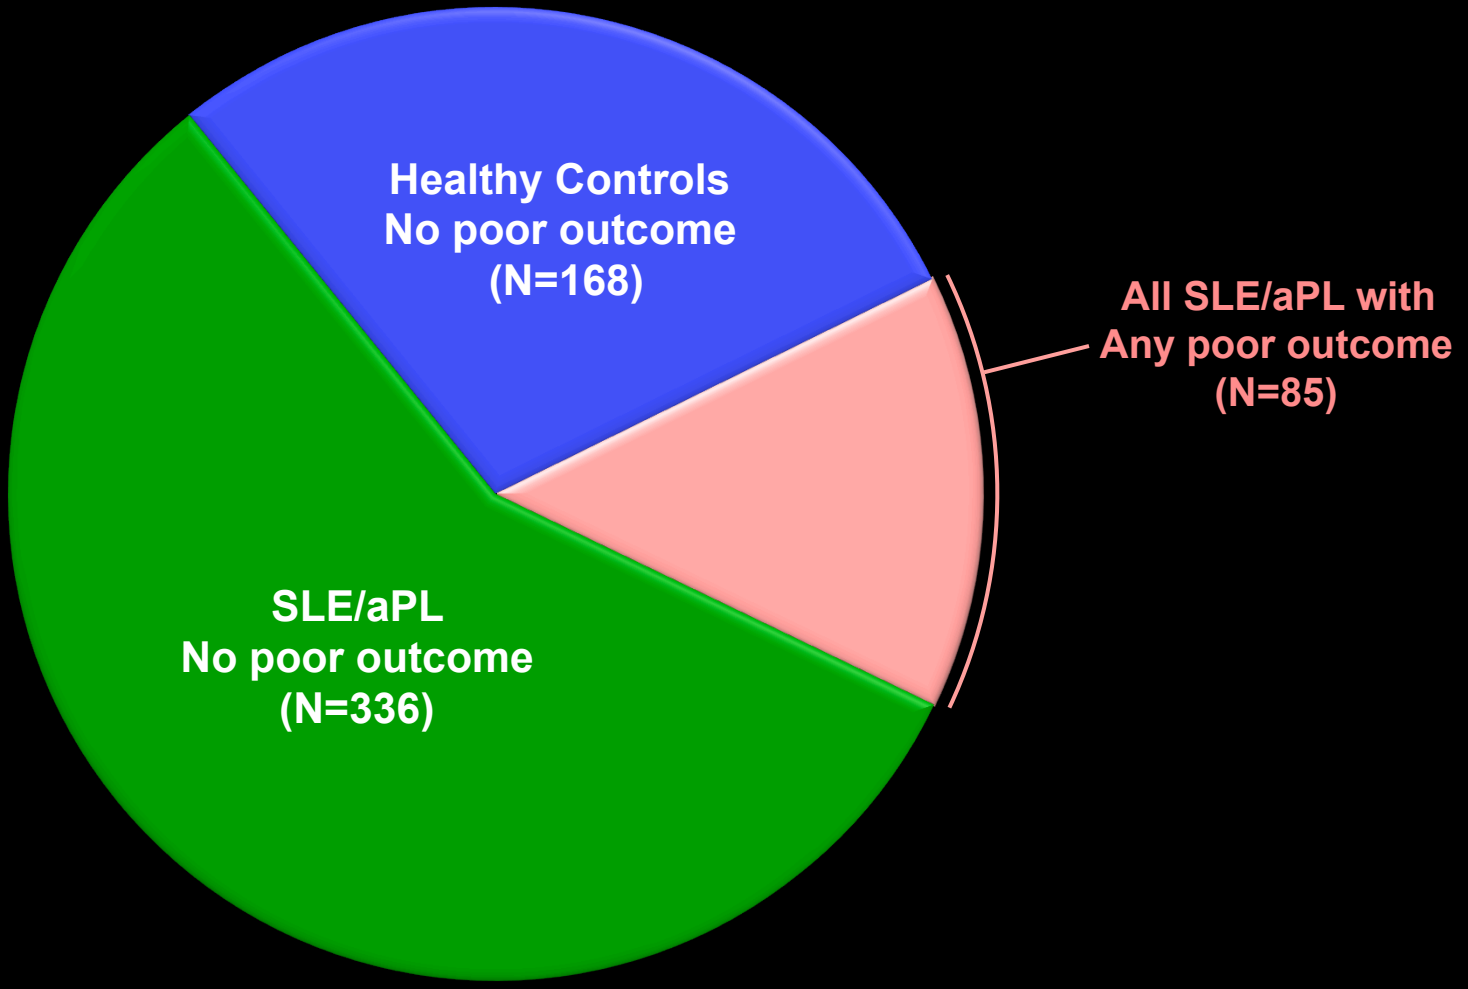
4. Rana S 2012. Circulation 125:911
5. Qazi U 2008. Lupus 35: 631

Hypothesis

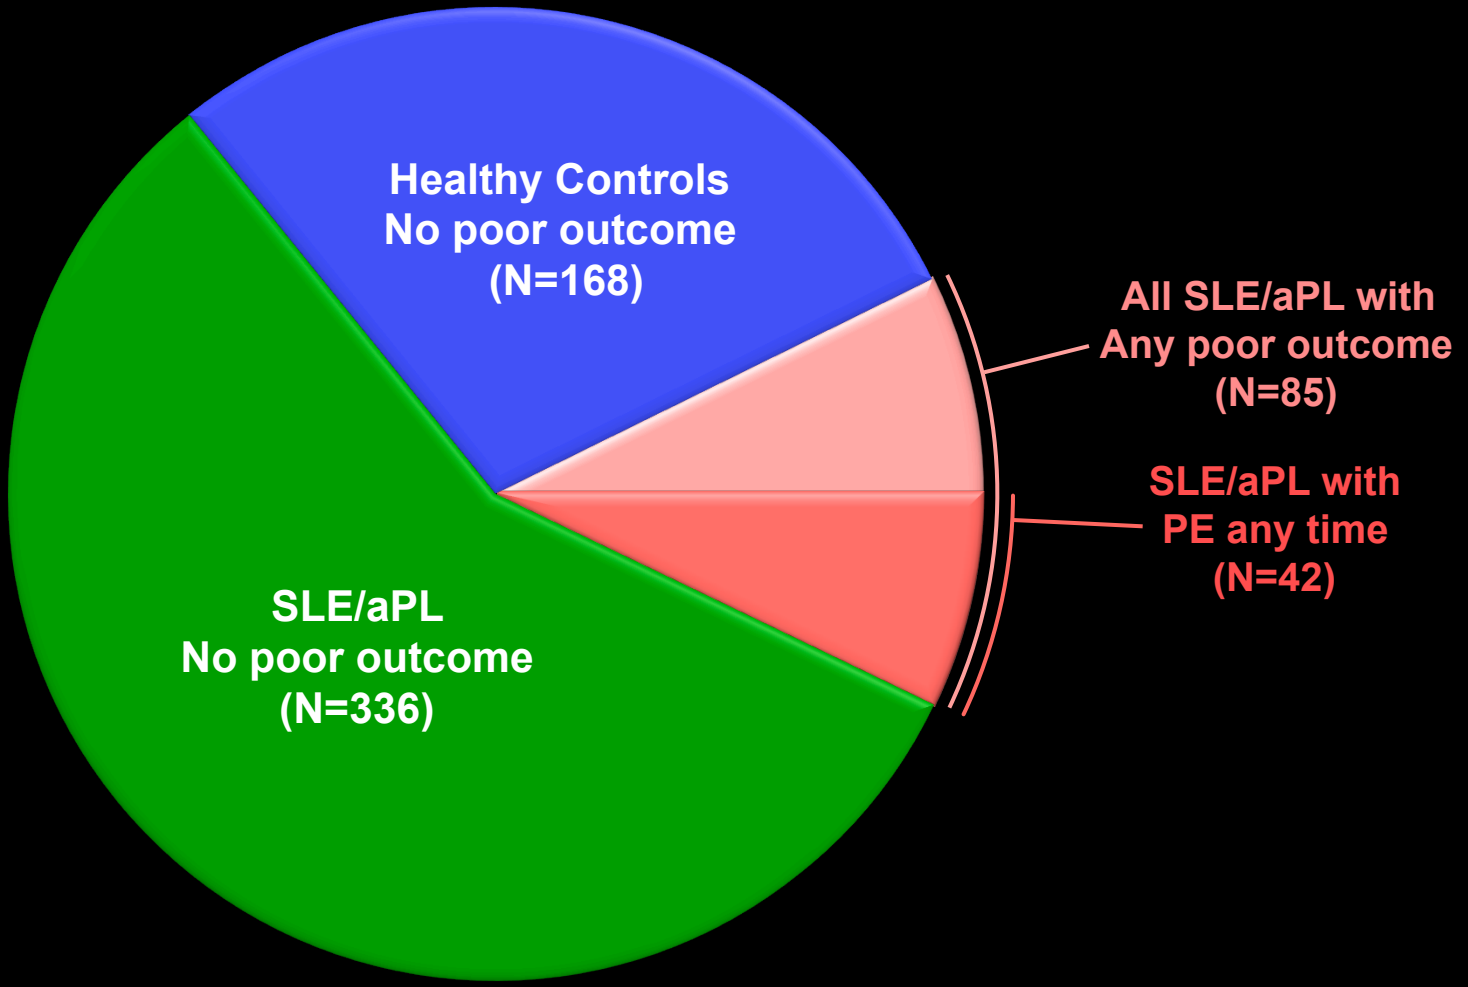
Elevated levels of anti-angiogenic factors early in pregnancy predict poor pregnancy outcomes in patients with SLE and/or APL

HOSPITAL FOR SPECIAL SURGERY

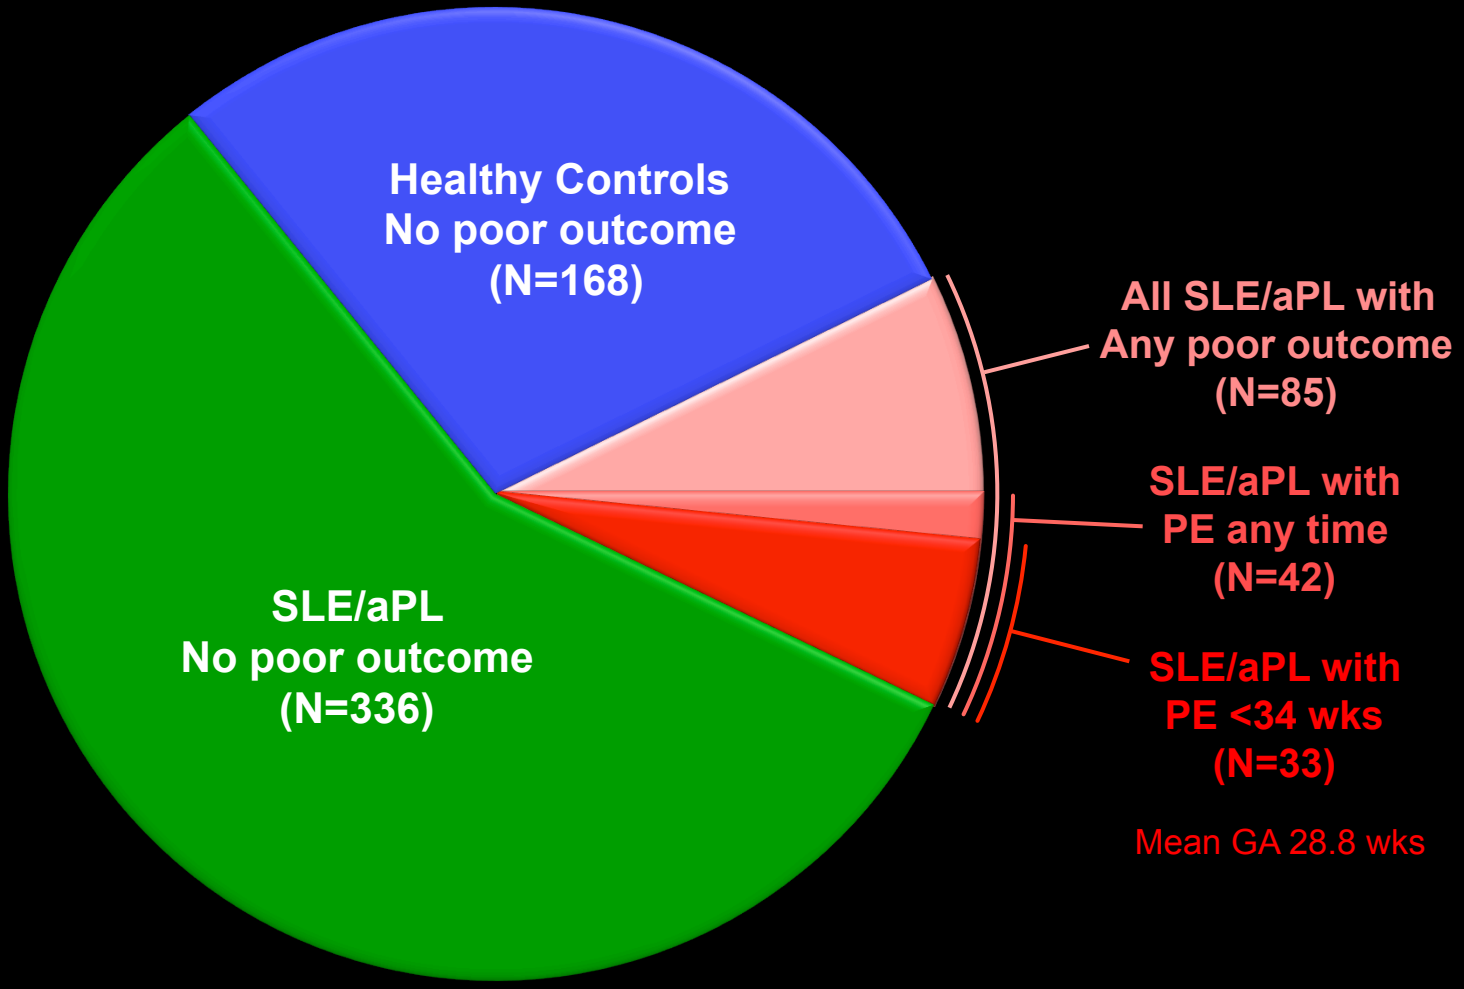
Patient Stratification by Pregnancy Outcome



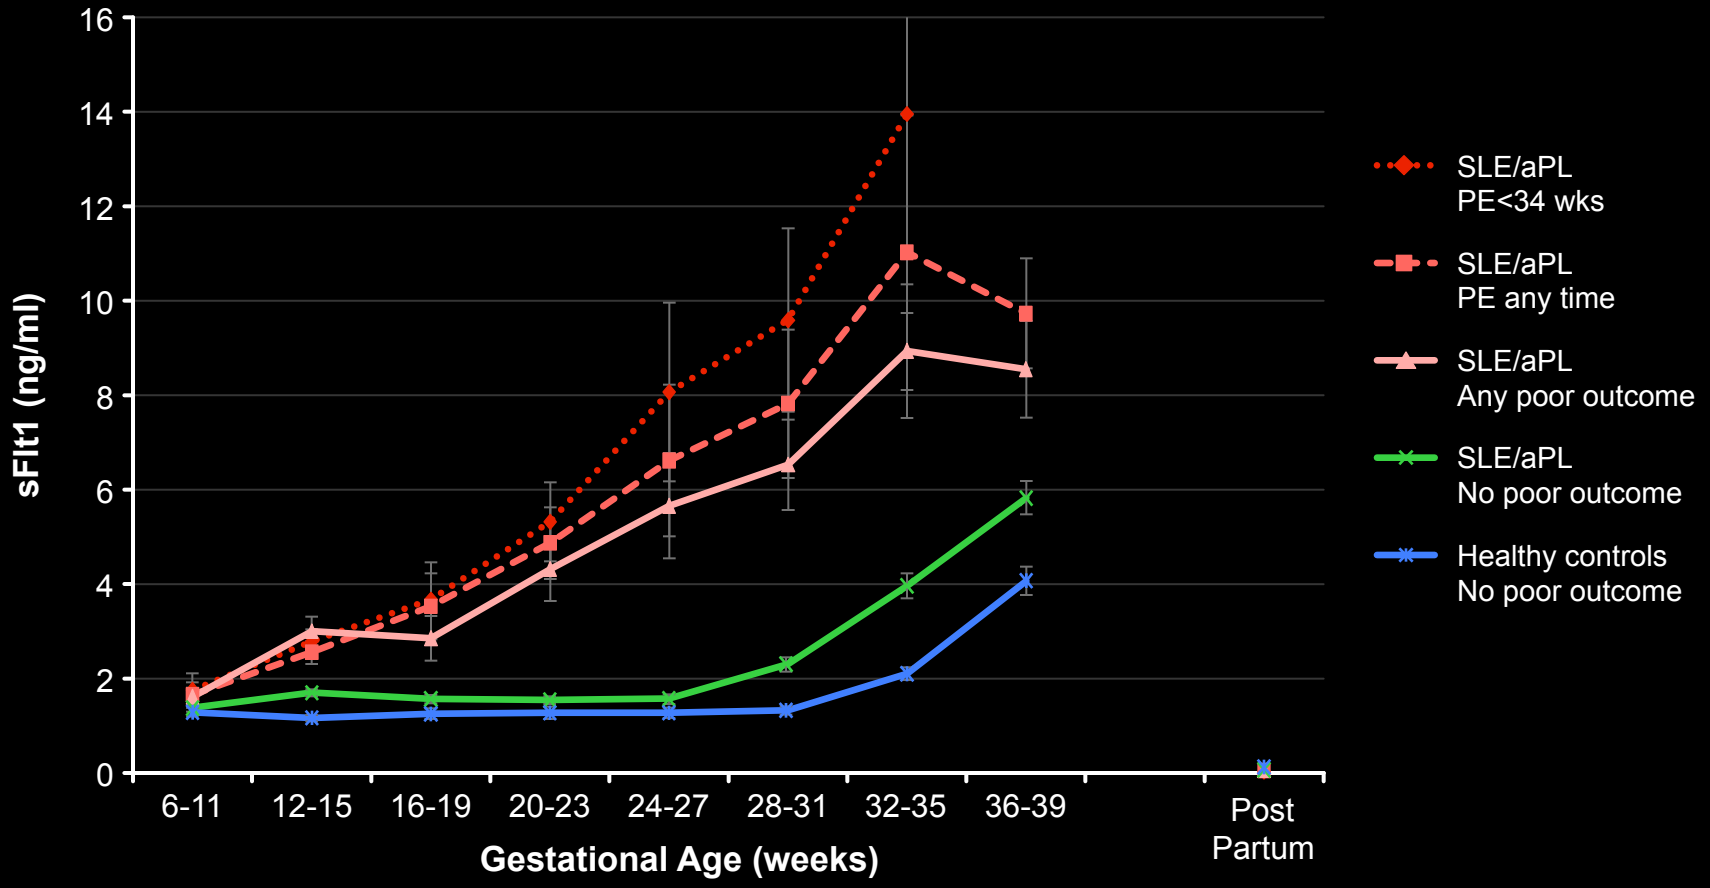
Patient Stratification by Pregnancy Outcome



Patient Stratification by Pregnancy Outcome

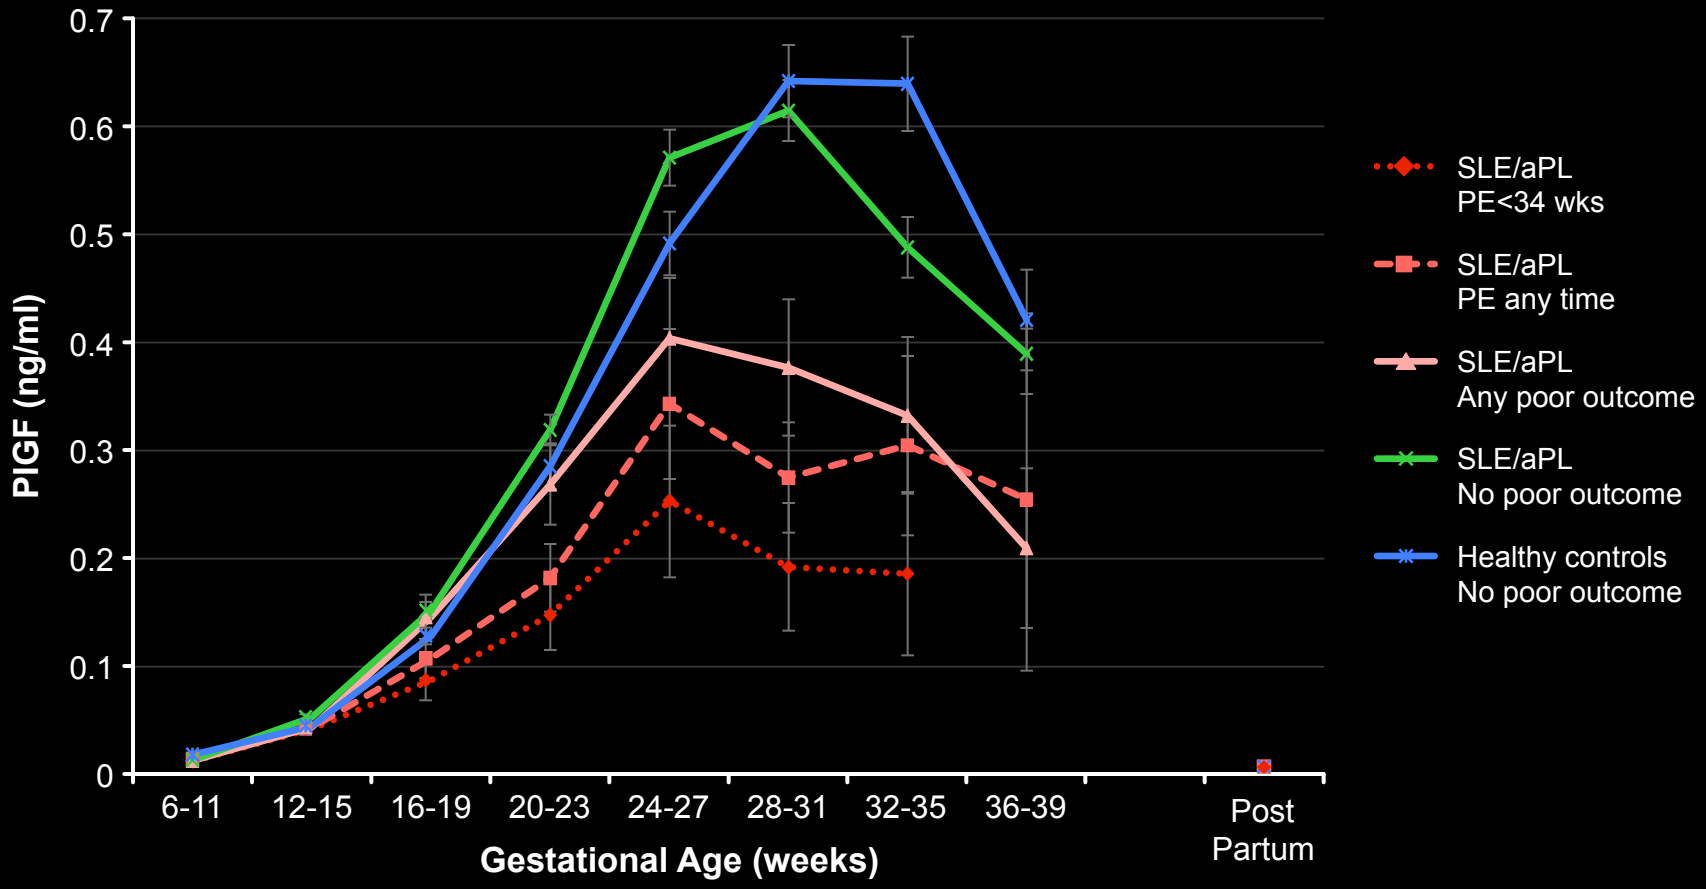


Elevated sFlt1 Precedes Poor Outcomes



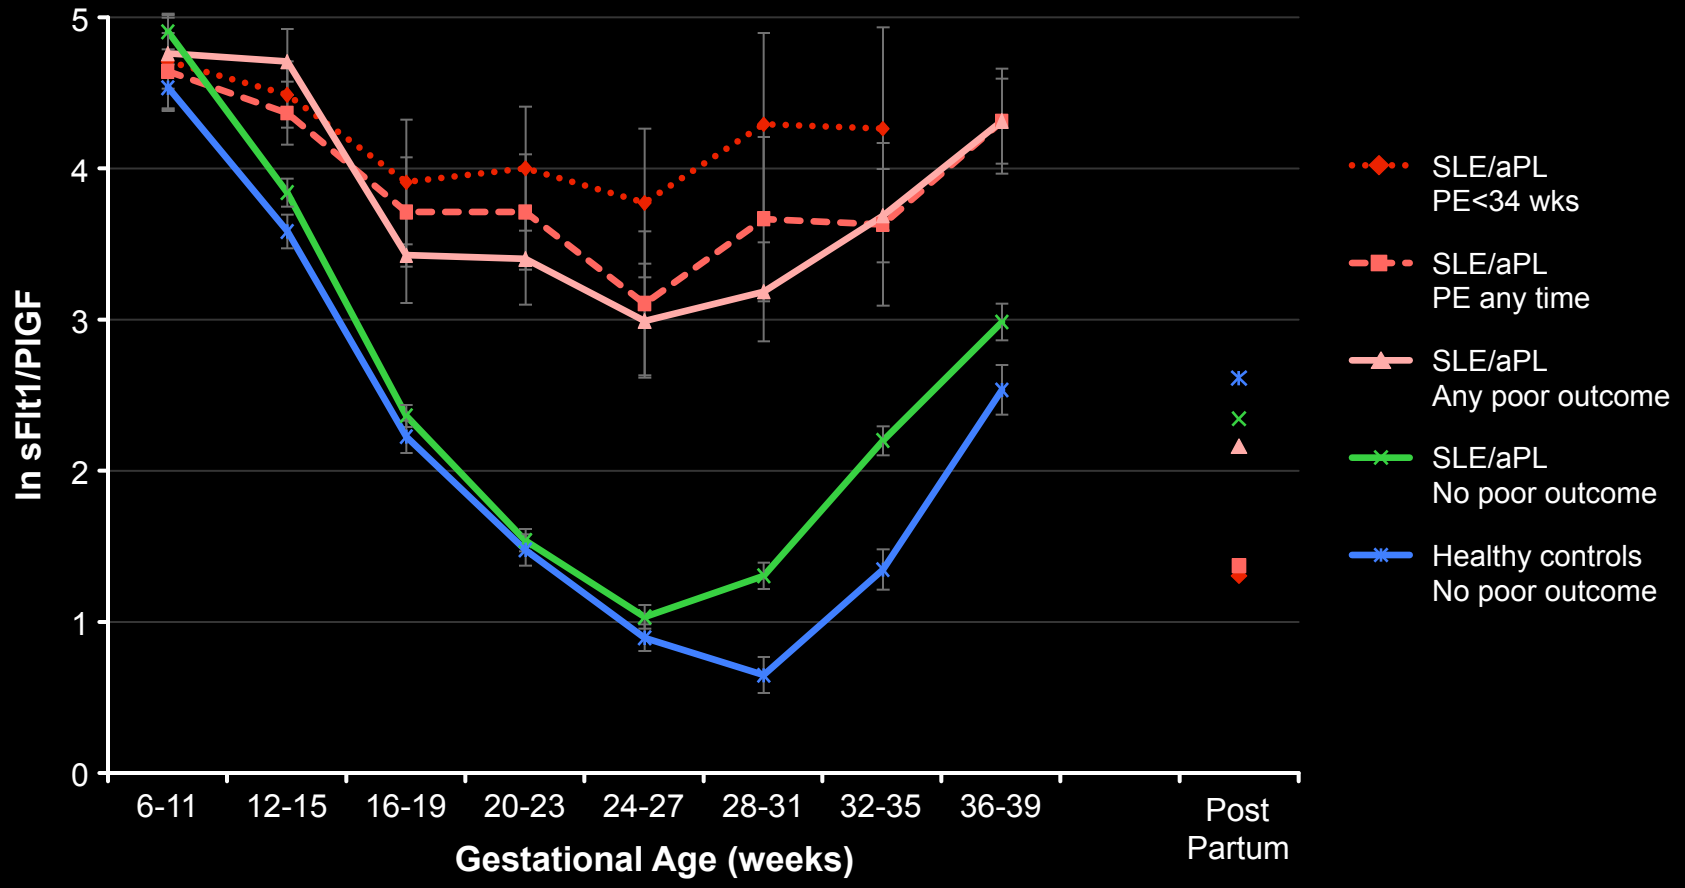
- sFlt1 was significantly higher from 12 - 31 weeks in SLE/aPL patients with PE<34wks, PE anytime, and any poor outcomes compared to SLE/aPL patients with no poor outcome
- Rate of increase in sFlt1 from 12 - 31 weeks was higher in SLE/aPL patients with PE<34wks, PE anytime, and any poor outcome compared to SLE/aPL patients with no poor outcome ($p < 0.0001$ all comparisons)

Lower PIGF is Associated with Poor Outcomes



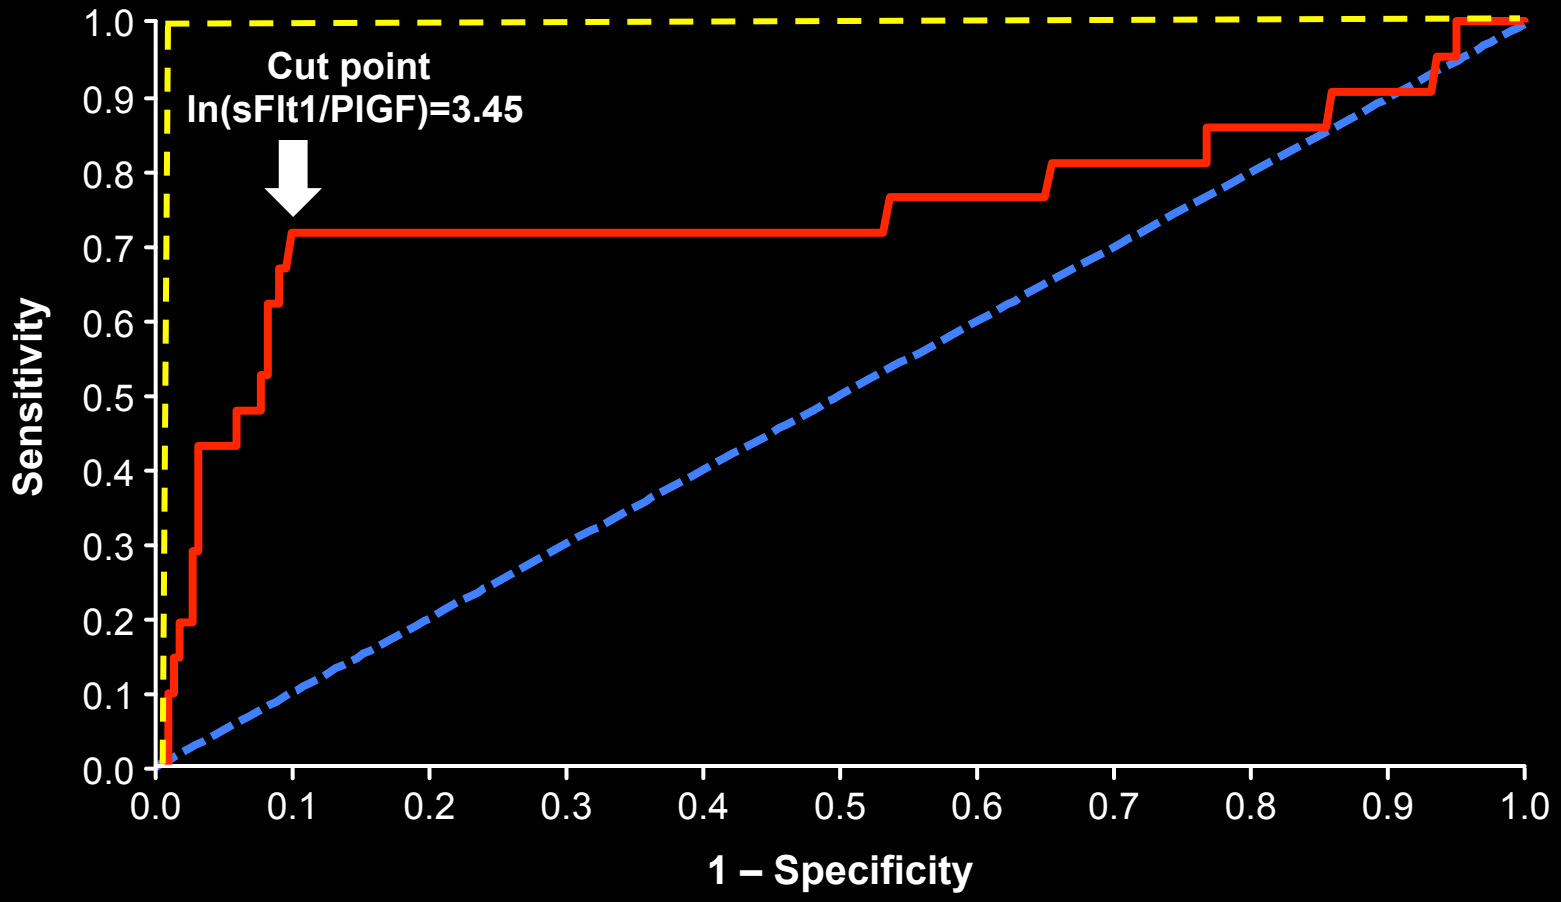
- PIGF was significantly lower in most comparisons from 16 - 31 weeks in SLE/aPL patients with PE<34 wks, PE anytime, and any poor outcomes compared to SLE/aPL patients with no poor outcome
- Rate of increase in PIGF from 12 - 31 weeks was lower in SLE/aPL patients with PE<34 wks, PE anytime, and any poor outcome compared to SLE/aPL patients with no poor outcomes ($p < 0.0001$ all comparisons)

Elevated sFlt1/PlGF is Associated with Poor Outcome



- Ln (sFlt1/PlGF) was significantly higher from 12 - 35 weeks in SLE/aPL patients with PE<34 wks, PE anytime, and poor outcomes compared to SLE/aPL patients with no poor outcome
- Rate of decrease in ln(sFlt1/PlGF) from 12 - 31 weeks was less in SLE/aPL patients with PE<34 wks, PE anytime, and no poor outcomes compared to SLE/aPL patients with no poor outcomes ($p < 0.0001$ all comparisons)

ROC Curve for PE<34 weeks using ln(sFlt1/PlGF) at 16-19 weeks' gestation



Area Under the Curve = 0.74

Performance of ln(sFlt1/PlGF) > 3.45 at 16-19 weeks as a Screening Test for PE<34 weeks

Sensitivity (true pos)	71%
Specificity (true neg)	90%
Positive Predictive Value	41%
Negative Predictive Value	97%
Relative Risk	13.8 (95% CI 5.7-33.2)

All subjects with aPL/SLE
Comparison group = aPL/SLE without PE<34 weeks

Conclusion

- In SLE and/or aPL-positive patients, alterations in the balance of angiogenic factors early in pregnancy are strongly associated with subsequent preeclampsia and other poor outcomes.
- That angiogenic imbalance is associated with a spectrum of poor pregnancy outcomes (e.g., growth restriction, preterm delivery, etc.) suggests common pathogenesis.
- Low sFlt1/PlGF ratios, as well as low sFlt1 or high PlGF levels, can reassure physicians and patients that preterm preeclampsia is unlikely.
- Ratios of sFlt1/PlGF may be used as early 16-19 weeks' gestation for risk stratification in future prevention trials.

HOSPITAL FOR SPECIAL SURGERY

PROMISSE Discovery 4

- Mutations in complement pathway genes that lead to uncontrolled complement activation are associated with preeclampsia in pregnant patients with SLE and/or aPL antibodies.
